

Application Note AN-PAN-1042

Online trace analysis of anions in the primary circuit of nuclear power plants

Water-steam circuits in fossil and nuclear power plants are inherently prone to corrosion, as metal components are constantly in contact with water. Measures to monitor or prevent corrosion are crucial in this context. In nuclear power plants, pressurized water reactors (PWR) are generally designed with a third water circuit in addition to the two found in conventional thermal power plants. In this so-called «primary circuit», the primary coolant water is

pumped under high pressure to absorb heat generated by nuclear fission, further transferring this heat to the secondary circuit. The PWR ensures that radioactive materials remain contained and do not disperse to the secondary circuit and therefore potentially to the environment. This additional water circuit entails some specific requirements regarding chemical analysis and monitoring.

Figure 1. Diagram of a 3-water circuit nuclear power plant with stars noting areas where online process analysis can be integrated into the system.

Anions corrode metals under high temperature and pressure; therefore, their concentrations must be monitored at all times. Since even traces can have devastating consequences, it is essential to use an analysis method that is appropriately sensitive. The analytical challenge in the primary circuit is detection of anions in the $\mu\text{g/L}$ range alongside gram quantities of boric acid (H_3BO_3) and lithium hydroxide (LiOH). In addition to the standard anions – **fluoride**, **chloride**, **nitrate**, and **sulfate** – important organic degradation

products such as **glycolate**, **formate**, and **acetate** can be present, indicating defective ion exchangers that are used to condition the boiler feed water. Phosphates are often added in order to prevent corrosion. Phosphates form corrosion-resistant protective films on metal surfaces, and cracks and defects are phosphatized in their presence. For this reason, it is often necessary to monitor the **phosphate** concentration as well.

Figure 2. Water sample from the primary circuit of a pressurized water reactor containing 2 g/L H₃BO₃ and 3.3 mg/L LiOH spiked with 2 µg/L anions; preconcentration volume: 2000 µL

APPLICATION

Precise, reliable trace analysis requires the method to be automated as much as possible. Metrohm Process Analytics offers a complete solution for this task: the **2060 Ion Chromatograph (IC) Process Analyzer** featuring combined Inline Preconcentration and Inline Matrix Elimination. With one injection, the 2060 IC is able to measure numerous ionic compounds in aqueous media from ng/L to % concentrations. The analysis system is fed directly and continuously with samples via a bypass in the process. Automatic calibration guarantees excellent detection limits, a high reproducibility, and excellent recovery rates.

The 2060 IC Process Analyzer provides alarms if preset warning or intervention concentration limits are reached, helping to save costs by preventing irreparable damage due to corrosion. The 2060 IC Process Analyzer can monitor both anions and cations, giving a comprehensive overview of the water circuit chemistry. The possibility to connect one analyzer to up to 20 sample streams means multiple areas within water-steam circuits in a power plant can be monitored by a single instrument. With a built-in eluent production module and optional PURELAB® flex 5/6 from ELGA® for pressureless ultrapure water, the 2060 IC Process Analyzer can be configured to run trace anion analyses autonomously for up to several weeks.

The analysis is carried out fully automatically using a combination of Inline Matrix Elimination (for the H_3BO_3) and Inline Neutralization (for the LiOH). Analyte detection is by conductivity.

REMARKS

Analyzing these trace anions allows the parallel determination of **chromate**, which is a potential

corrosion product.

Figure 3. The 2060 IC Process Analyzer is available with either one or two measurement channels, along with integrated liquid handling modules and several automated sample preparation options.

BENEFITS FOR IC IN PROCESS

- Inline eluent preparation ensures consistently stable baselines
- Safe working environment and automated sampling
- Protect valuable **company assets** (e.g. pipes, PWR, and turbines, which are prone to corrosion)
- High precision analyses for a wide spectrum of analytes with multiple types of detectors

CONFIGURATION

2060 IC Process Analyzer

L'appareil d'analyse **2060 Ion Chromatograph (IC) Process Analyzer** de Metrohm Process Analytics repose sur le concept de la plate-forme modulaire 2060. Cette architecture modulaire permet de séparer les armoires dans différentes zones d'un site et de connecter jusqu'à 20 flux d'échantillons en vue d'une analyse séquentielle à plusieurs endroits d'un site afin de gagner du temps.

Cet appareil d'analyse n'impose aucune restriction concernant le matériel, les logiciels et la personnalisation des applications. Du module de production d'éluant en continu aux modules par voie humide pour le conditionnement des échantillons, en passant par les multiples blocs de détection CI, le 2060 IC Process Analyzer offre toutes les options nécessaires pour toute application industrielle.

Le logiciel 2060 est une solution logicielle « tout-en-un » qui contrôle l'appareil d'analyse afin d'effectuer des analyses de routine selon différentes méthodes de maniement, différentes fiches horaires et différents graphiques de tendance. En outre, les protocoles de communication du processus (par ex. Modbus ou Discrete I/O) étant variés, le logiciel 2060 peut être programmé pour envoyer automatiquement des retours d'information et des alarmes au système chargé de la procédure et pour prendre les mesures nécessaires (par ex., répéter la mesure d'un échantillon ou démarrer un cycle de nettoyage). Toutes ces caractéristiques assurent un diagnostic entièrement automatique de la procédure industrielle, 24 heures sur 24, 7 jours sur 7.
